

NAAN MUDHALVAN PROJECT PORTFOLIO | PHASE 7 OF 8

Phase 7: Production Deployment & Update Set Management

Project: Auto Ticket Classification using Flow Designer | **Governance:** ServiceNow Change Management & XML Packaging

1. Update Set Lifecycle & Promotion Strategy

In enterprise ServiceNow operations, changes made within a sub-production instance (Developer Sandbox) must never be re-keyed manually into Production. ServiceNow **Update Sets** capture table schemas, field attributes, choice lists, dictionary overrides, and Flow Designer configurations into portable XML artifacts.

2. Procedure for Finalizing & Exporting Development

Activity 7.1: Completing the Update Set

1. Navigate to: **System Update Sets** → **Local Update Sets**.
2. Open the active development container: Project Update Set.
3. Review the **Customer Updates** related list to confirm that all custom fields, dependencies, and flow records are tracked.
4. Change field **State**: from In progress to Complete.
5. Click **Save**. Once set to Complete, no accidental modifications can contaminate the set.

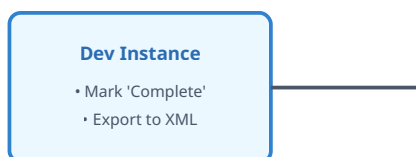

Activity 7.2: XML Extraction & Archival

1. With the completed Update Set open, scroll to *Related Links*.
2. Click **Export to XML**.
3. The browser downloads an XML document encapsulating all custom logic:

```
sys_remote_update_set_[Project_Update_Set].xml
```

4. Secure the file in repository version control for project review and cross-instance migration.

3. Target Instance Deployment Pipeline

4. Post-Deployment Verification Checklist

- **Schema Verification:** Confirm table `u_incident_workflow` exists with all 9 attributes.
- **Choice Matrix Integrity:** Validate that dependent choice values operate seamlessly on the live form.
- **Flow Compilation:** Inspect Flow Designer in target instance to ensure the flow is published and in an **Active** state.
- **Email Engine Connectivity:** Confirm outbound SMTP mail server connectivity for caller receipt generation.
